

CONCLUSION (STATED)

Text 1

Hundreds of Queenslanders are bitten by snakes each year, with cases peaking during the warmer months. Already this year, nearly 100 snake bites have been reported to Queensland Ambulance Service (QAS), including three in a single night. While fatal cases are rare, they do occur, as seen in the recent death of a 60-year-old man in Lockyer Valley after a suspected brown snake bite. Biologist Christina Zdenek from the University of Queensland warns against underestimating snakes and advises calling professionals for removal rather than attempting to handle them. Most bites happen on the leg when people try to move a snake, which is both dangerous and illegal. She also highlights the ecological importance of snakes in controlling rodent populations.

no 2
untuk mengontrol populasi tikus hanya sekitar 14 case

Despite the consistent number of snake bites in Queensland—846 in 2022 and 860 the year before—Dr. Zdenek emphasizes that deaths should be preventable. Australia has effective first aid methods, such as compression bandages that slow venom spread, and high-quality antivenom readily available in hospitals. However, increasing urban development near bushland and the rise of social media documentation make snake encounters seem more frequent than before. More people working from home may also lead to more sightings, but there is no definitive data on whether snake populations are growing or declining.

To stay safe, Queenslanders are advised to take precautions, especially during summer when snake activity increases. The QAS recommends avoiding long grass, wearing sturdy shoes, and having quick access to a compression bandage, particularly in remote areas where medical help may take longer to arrive. If bitten, victims should avoid washing the wound, as hospitals may need to test for venom traces to determine the snake species. Since puncture marks may not always be visible, other signs such as scratches or bleeding should also be considered. Applying a firm bandage over the bite, immobilizing the limb, and seeking immediate medical attention can be lifesaving.

apa yang dapat disimpulkan mengenai gigitan ular di Queensland

1. What can be concluded about snake bites in Queensland?
 - A. Snake bites are becoming more frequent each year.
 - B. Most snake bites happen due to human attempts to keep snakes.
 - C. Fatal snake bites are a leading cause of death in Australia.
 - D. Queensland has no proper medical response to snake bites.

relative stabil
sedikit fatal

2. What can be concluded about handling snakes?

- ☒ A. It is illegal, dangerous, and should be left to professionals.
- B. People should relocate snakes themselves to prevent bites.
- C. Killing snakes is the best way to ensure safety.
- D. Snakes are slow-moving and easy to handle safely.
- E. Handling snakes is only dangerous for people without experience.

3. What is the passage's main point about snake bite prevention?

- A. Snake bites are unavoidable and should not be a major concern.
- B. Carrying a snake repellent spray is the best way to stay safe.
- ☒ C. Avoiding long grass and wearing sturdy shoes can help reduce risks.
- D. Keeping snakes as pets can help people learn how to handle them.
- E. Snakes usually do not bite unless provoked, so precautions are unnecessary.

Peran ular dalam ekosistem

4. What does the passage conclude about the role of snakes in the ecosystem?

- ☒ A. They help control rat populations, making them important to the environment.
- B. They serve no real purpose and are mostly a danger to humans.
- C. The best way to maintain balance in nature is to remove venomous snakes.
- D. Snakes are overpopulated and should be controlled by the government.
- E. The ecosystem can function just as well without venomous snakes.

5. What can be concluded about first aid for snake bites?

- ☒ A. Compression bandages help slow venom spread and buy time for medical treatment.
- B. Washing the wound immediately is the most important step.
- C. Moving as much as possible after a bite increases the chance of survival.
- D. Most snake bites require no medical attention if treated quickly at home.
- E. Snake bites are untreatable if the victim does not reach a hospital in 30 minutes.

lebih sering

6. What can be inferred about why snake encounters seem more frequent today?

- A. The snake population is rapidly increasing across Australia.
- ☒ B. More people live near bushland and document encounters on social media.
- C. Climate change has made snakes more aggressive and active.
- D. Government policies have led to more snakes being released into urban areas.
- E. People are less educated about snake safety than they were before.

7. What is an implied reason why some people still die from snake bites despite available medical treatment?

- ☒ A. They may not receive first aid or medical help quickly enough.
 - B. Antivenom is not effective against most Australian snakes.
 - C. Many hospitals refuse to treat snake bite victims.
 - D. The government does not fund enough snake bite research.
 - E. Compression bandages are too expensive for most Australians.
8. Why might more people be at risk of snake bites now compared to the past?
- A. Urban development is expanding into snake habitats.
 - B. Snake migration patterns have shifted due to human activity.
 - C. People are actively attracting snakes by feeding them.
 - D. Government protection laws have led to an increase in snake populations.
 - E. Hospitals are less prepared to treat snake bites than they used to be.

9. What can be inferred about the effectiveness of Australia's emergency response to snake bites?

- ☒ A. It is well-developed and helps prevent most deaths.
- B. It is outdated and does not effectively prevent fatalities.
- C. It only works well in urban areas with access to hospitals.
- D. It has not improved in the last decade.
- E. It is the least effective in regions with a high snake population.

10. What is an unstated benefit of increased awareness about snakes?

- ☒ A. More people are learning how to react safely in snake encounters.
- B. Snake populations are decreasing due to better removal methods.
- C. People are no longer afraid of venomous snakes.
- D. The government has banned snake removals to protect them.
- E. Social media posts about snakes have made people panic unnecessarily.

Text 2

Saliva is far more than a simple lubricant for the mouth; it plays a critical role in shaping our sensory experiences with food and drink. Composed of 99% water, saliva interacts with everything we eat, influencing flavors, textures, and even our preferences. It contains enzymes like amylase and lipase that begin digestion and salivary proteins that lubricate each bite. These components dissolve tastants—the chemical compounds responsible for taste—allowing them to reach our taste buds and

trigger flavor sensations. Food scientist Jianshe Chen highlights that what we truly savor is not just the food itself, but a mixture of food and saliva, which mediates the chemical and sensory interactions in the mouth.

Beyond taste, saliva profoundly impacts how we perceive aroma and texture, both of which are central to flavor. When we chew, some flavor molecules dissolve in saliva, while others waft into the nasal cavity, contributing to aroma detection. Differences in salivary flow rates or protein composition, such as mucins, can lead to vastly different flavor experiences among individuals. Saliva also influences the sensation of texture, such as the astringency experienced with red wine. Tannins in wine, for example, interact with salivary proteins, reducing lubrication and creating the dry mouthfeel often associated with certain foods or beverages.

Recent studies underscore the importance of saliva as a mediator between food, the mouth, and the brain. Saliva not only affects how food moves in the mouth but also determines how flavors and textures are perceived. This is evident in phenomena like flat soda tasting sweeter than fizzy soda, where saliva inhibits bubbles from interfering with sugar molecules reaching the taste buds. Understanding these complex interactions could pave the way for designing healthier, more enjoyable foods by tailoring the sensory experience to enhance flavor, aroma, and texture.

11. What conclusion does the passage present about saliva's role in food perception?

- A. Saliva is primarily composed of enzymes that digest food.
- B. Saliva serves as a lubricant with no significant effect on flavor or texture.
- ☒ C. Saliva mediates and enhances the sensory experience of food, including taste, aroma, and texture.
- D. Differences in salivary flow rates lead to identical flavor experiences among individuals.
- E. Saliva's role is limited to providing hydration for the mouth.

12. Based on the passage, what can be inferred about the potential for future food design?

- A. Future food designs will focus solely on reducing astringency in foods like wine.
- ☒ B. Researchers may develop foods that consider saliva's role to improve flavor and texture.
- C. Saliva composition is irrelevant to creating enjoyable food experiences.
- D. The interaction between saliva and food is too complex to be practically applied in food design.
- E. Flavor preferences are determined entirely by the ingredients of the food, not saliva.

13. What can be concluded from the relationship between saliva and tastants?

- A. Saliva prevents tastants from dissolving in the mouth.
- ☒ B. Tastants dissolve in saliva to reach taste buds and trigger flavor sensations.
- C. Tastants bypass saliva to directly reach the taste buds.
- D. Tastants are unaffected by the enzymes in saliva.
- E. Tastants are the primary component of saliva.

14. What can be inferred about how individuals perceive flavors differently?

- A. Everyone perceives flavors the same way, regardless of saliva composition.
- ☒ B. Variations in saliva flow rate and protein composition contribute to different flavor experiences.
- C. Saliva composition has no measurable effect on flavor perception.
- D. Flavors are entirely determined by the ingredients in food and unrelated to saliva.
- E. People with high saliva flow rates cannot detect taste molecules.

15. What can be concluded about saliva's role in texture perception?

- A. Saliva determines whether food tastes sweet or sour.
- ☒ B. Saliva influences the feeling of dryness or lubrication in the mouth.
- C. Saliva dissolves food molecules for the taste buds to detect.
- D. Saliva prevents bubbles from blocking taste receptors.
- E. Saliva regulates the flow of aromatic molecules into the nasal cavity.

16. What can be inferred about flat soda tasting sweeter than fizzy soda?

- A. Saliva prevents sugar molecules in flat soda from reaching taste buds.
- ☒ B. Saliva allows sugar molecules in flat soda to reach taste buds more effectively due to the absence of bubbles.
- C. Saliva blocks all taste sensations in fizzy soda.
- D. Flat soda lacks the enzymes necessary to trigger sweetness detection.
- E. Bubbles in fizzy soda amplify the sweetness by interacting with saliva.

17. What can be inferred about saliva's influence on the design of healthier foods?

Pengaruh saliva untuk desain pada makanan sehat

- ☒ A. Foods can be designed to enhance their interaction with saliva to improve flavor perception.
- B. The complexity of saliva's role in taste makes it impossible to consider in food design.
- C. Saliva is only important for digesting food, not for designing healthier options.
- D. Healthier foods should focus on eliminating saliva's influence on texture.
- E. Saliva's role in food processing is too minor to impact food design significantly.

18. What role do tannins in wine play, as explicitly stated in the passage?

- A. Tannins dissolve in saliva and enhance lubrication in the mouth.
- ☒ B. Tannins reduce saliva's lubricating properties, causing a dry mouthfeel.
- C. Tannins block saliva from reaching the taste buds.
- D. Tannins amplify the sweetness of wine by interacting with saliva.
- E. Tannins neutralize the enzymes in saliva.

19. What does the passage suggest about red wine's astringent texture?

- A. The wine's tannins directly dry out the mouth.
- ☒ B. Saliva's lubrication is reduced because tannins precipitate its proteins.
- C. Tannins neutralize enzymes in saliva, creating the dry sensation.
- D. Astringency is caused by saliva amplifying the wine's acidity.
- E. Red wine interacts with saliva to enhance sweetness rather than texture.

20. What can be concluded about the enzymes in saliva?

- A. They dissolve all flavor molecules in food.
- ☒ B. They help begin the digestion process in the mouth.
- C. They neutralize acids in food to protect the teeth.
- D. They enhance the aromas of food.
- E. They are the only components of saliva influencing flavor.
